
In our project we investigate the interactions between reward shaping and imitation learning. Specifically, we perform imitation learning on heavily biased data

In our project we investigate whether imitation learning on biased data can reduce the need of research question: pretrain with imitation learning on limited data (not all desired behaviour), tradeoff between guiding the model towards winning strategies, and loss of plasticity preventing the model to learn new concepts after imitation learning

Pretraining and loss of Plasticity

Why Chess?

For a successful chess agent we expect it perform well in two areas:
succeed at tactics: that is short-term thinking succeed at strategy:

Why chess could pose a challenge

complex game, with low probability of the model winning without any guidance. Thus we

Methods

Train RL model with
